

**System and Method for
Concurrent Security Connections**

ABSTRACT

A system and method for concurrent security
5 connections is presented. An association table is used
that includes a list of active credentials. An active
credential includes information such as user id and
password information for a given domain. The active
credential may also include dynamic data that is retrieved
10 from a user, such as a pseudo-random code or a fingerprint
scan. The active credential is sent to a domain, or the
managing server of the domain, when domain access is
requested. This access request does not involve the user
of the client unless dynamic input data is requested.
